

**Maximum sliding window.** Given an array of integers  $arr$  and a sliding window of size  $k$  ( $k \leq n$ ), find maximum sliding window; sliding window starts from 0th index of the array and moves one step to the right side at each iteration.

$arr = [2 \quad 4 \quad 1 \quad 3 \quad 0 \quad 12]$

$k = 3$  (size of the window) 

--	--	--

**Question:** How many window can we have with an array of size  $n$  and window size of  $k$ ?

$arr = [ \overset{0}{2} \quad \overset{1}{4} \quad \overset{2}{1} \quad \overset{3}{3} \quad \overset{4}{0} \quad \overset{5}{12} ]$ ;  $n = 6$ ;  $k = 3$ ;

Iteration

sliding window

1

$arr = [ \overset{0}{2} \quad \overset{1}{4} \quad \overset{2}{1} \quad \overset{3}{3} \quad \overset{4}{0} \quad \overset{5}{12} ]$

2	4	1
---	---	---

2

$arr = [ \overset{0}{2} \quad \overset{1}{4} \quad \overset{2}{1} \quad \overset{3}{3} \quad \overset{4}{0} \quad \overset{5}{12} ]$

4	1	3
---	---	---

3

$arr = [ \overset{0}{2} \quad \overset{1}{4} \quad \overset{2}{1} \quad \overset{3}{3} \quad \overset{4}{0} \quad \overset{5}{12} ]$

1	3	0
---	---	---

4

$arr = [ \overset{0}{2} \quad \overset{1}{4} \quad \overset{2}{1} \quad \overset{3}{3} \quad \overset{4}{0} \quad \overset{5}{12} ]$

3	0	12
---	---	----

5

$arr = [ \overset{0}{2} \quad \overset{1}{4} \quad \overset{2}{1} \quad \overset{3}{3} \quad \overset{4}{0} \quad \overset{5}{12} ]$

0	12	
---	----	--

out of index

It can be observed that with  $n = 6$  and  $k = 3$ , we are having  $4 (n - k + 1)$  sliding windows.

## Algorithm:

- keep one reference index

- Use one inner loop

- Compare the reference node to each internal loop element which has the size of one window

- append the largest to the sliding window.

- Increment the outer loop reference by one after each complete inner loop completion.

```
def maxwindow(arr, n, k):
```

```
    window = []
```

```
    for i in range(n - k + 1):
```

```
        ref = arr[i]
```

```
        for j in range(i + 1, i + k):
```

```
            ans = max(ref, arr[j])
```

```
        window.append(ans)
```

```
    return ans
```

**Analysis:** For outer loop, we do at most  $(n-k+1)$  operations and for inner loop  $(i+k)$  operation, Hence the time complexity can be computed as follow.

$$O(\text{outer loop}) * O(\text{inner loop})$$

$$\Rightarrow O(n-k+1) * O(i+k) \Rightarrow \text{Ignoring lower order terms}$$

$$\Rightarrow O(n) * (k)$$

## optimal solution using deque:

arr = [ <sup>0</sup>2 <sup>1</sup>4 <sup>2</sup>1 <sup>3</sup>3 <sup>4</sup>0 <sup>5</sup>12 ];    n = 6;    k = 3;

arr = [ <sup>0</sup>2 <sup>1</sup>4 <sup>2</sup>1 <sup>3</sup>3 <sup>4</sup>0 <sup>5</sup>12 ]    2

arr = [ <sup>0</sup>2 <sup>1</sup>4 <sup>2</sup>1 <sup>3</sup>3 <sup>4</sup>0 <sup>5</sup>12 ]    ~~2~~ 4

current element  $\geq$  last element in deque:

Remove last element From deque:  
arr = [ <sup>0</sup>2 <sup>1</sup>4 <sup>2</sup>1 <sup>3</sup>3 <sup>4</sup>0 <sup>5</sup>12 ]    ~~2~~ 4 1

because 1 comes after 4, it is a possibility to be our answer.

arr = [ <sup>0</sup>2 <sup>1</sup>4 <sup>2</sup>1 <sup>3</sup>3 <sup>4</sup>0 <sup>5</sup>12 ]    ~~2~~ 4 ~~1~~ 3

1 comes before 3, and it is smaller than 3, cannot be our answer, because we want the largest in the range.

arr = [ <sup>0</sup>2 <sup>1</sup>4 <sup>2</sup>1 <sup>3</sup>3 <sup>4</sup>0 <sup>5</sup>12 ]    ~~2~~ 4 ~~1~~ 3 0

because 0 comes after 3, it is a possibility to be our answer.

i

arr = [ <sup>0</sup>2 <sup>1</sup>4 <sup>2</sup>1 

<sup>3</sup> 3	<sup>4</sup> 0	<sup>5</sup> 12
----------------	----------------	-----------------

 ]

~~2~~ ~~4~~ ~~1~~ ~~3~~ ~~0~~ 12

0 comes before 12 and it is smaller than 12. cannot be our answer, because we want the largest in the range.

our final answer is [4 3 12]

**Analysis:** for each element, we are doing addition, maybe removal or both.

in deque the above operations are done at  $O(1)$ .

2 operations at worst case scenario for n elements

Hence,  $T.C = O(2 * N) = O(N)$

```
def slidingWindow(arr, n, k):
```

```
    dq = deque()
```

```
    ans = [0] * (n - k + 1)
```

```
    // solve for the first window
```

```
    for i in range(k):
```

```
        while len(dq) > 0 and arr[i] > dq[-1]:
```

```
            dq.pop()
```

```
            dq.append(arr[i])
```

```
    ans[0] = deque[0]
```

```
    // for remaining elements, insert ith  
    and remove (i-k)th
```

```
    for i in range(k, n):
```

```
        while len(dq) > 0 and arr[i] > dq[-1]:
```

```
            dq.pop()
```

```
            if arr[dq[0]] == arr[i-k]:
```

```
                dq.popleft()
```

```
            dq.append(arr[i])
```

```
            ans[i - k + 1] = deque[0]
```

```
    return ans
```
